

## Prescribed Burning on Large Landholdings in the South During 1975

by Ragnar W. Johansen and William H. McNab<sup>1</sup>

Abstract. --Approximately 1.85 million acres of commercial timberland in large private and Federal holdings were prescription burned in the South during 1975. At least an additional 298,000 acres of wild land were burned for wildlife habitat and range improvement. Thus, in excess of 2.15 million acres of total wild land (timberland plus other wild land) was prescription burned on large landholdings in the South during 1975. This total does not include any prescription burning on small landholdings. Private industry burned 1.27 million acres, 40 percent for site preparation.

Keywords: Fire management, site preparation, fuel reduction.

Prescribed burning has long been a common treatment on forest land in the South, but the acreage treated has been unknown because no uniform system exists for reporting prescribed burning activity in most states. This Note reports the results of a survey of managers of large forest-land holdings. Managers were asked to give the acreage burned and the purpose of burning. Since most such treatments are done on large holdings, the data reported here represent a large but unknown percentage of all prescribed burning in the South.

Planners need this information to estimate the location and amount of smoke emissions in the region and to determine the portion of fire-prone area being protected annually by prescribed fire.

### SAMPLING METHODS

Information on area managed, extent of prescription burning, and purpose of burning in the South during 1975 was gathered in three ways, depending on what was already published and how easily land managers could be contacted.

The acreage of commercial forest in the National Forest System and in private industry holdings was obtained from a published report.<sup>2</sup> Prescribed burning statistics for National Forests were obtained from agency accomplishment reports.<sup>3</sup> Land managed and prescribed burned by other Federal agencies in the South, such as the Departments

<sup>3</sup>U.S. Department of Agriculture, Forest Service. Forest Service accomplishment report for National Forests in Region 8 during fiscal year 1976 (July 1, 1975- June 30, 1976). Washington, DC: U.S. Department of Agriculture, Forest Service; 1976.

of Defense, Fish and Wildlife Service, and National Park Service, was acquired by personally contacting the individual in charge of each major holding.

Data on burning by private industry in the South were obtained by sending a questionnaire to a sample of 230 land managers in 11 Southern States. Requested information included: (1) acres of forest land being managed, (2) total area prescription burned in 1975, and (3) area burned for site preparation. Kentucky and Oklahoma, often considered Southern States, were excluded because prescribed burning is not widely practiced in those States.

Burning on small private ownerships was excluded from this assessment. Reliable information for this ownership group is not available and will not become so until reporting systems similar to those now in effect in Florida and North Carolina are initiated in the other states.

#### AREA IN LARGE HOLDINGS

In 1975, the 11 States contained **184,107,000** acres of commercial forest land. Approximately 26 percent of this

acreage was in large Federal or forest industry holdings (table 1). Private industry managed some 18.9 percent of the commercial forest acreage. National Forests were a distant second in area managed with 5.8 percent.

#### PRIVATE INDUSTRY PRESCRIPTION BURNING

There were 76 responses to the questionnaires sent to private industry with at least one response from each of the States sampled (table 2). Respondents collectively managed about 10-3/4 million acres of timberland, which is about 31 percent of all industry-managed land in the South. Sample size, based on fraction of industry land accounted for in the sample, ranged from 4.7 percent in Florida to over 60 percent in Georgia, South Carolina, and Tennessee. By extrapolating the acreage prescription burned in each State, based on the sample received, a total of **1,273,600** acres was estimated for industry in the 11 sampled Southern States.

More than two-thirds of the prescription burning identified in the study was done by forest industry,

which burned 3.7 percent of its forest land in 1975 (table 3). Considerable land on National Forests and 200,150 acres of military timberland were burned. This area represents 13 percent of commercial timberland on military reservations. Most burning there

was done to reduce hazardous fuel buildup, and the trend on military reservations is toward increasing hazard-reduction burning. Based on actual prescribed-burning records from Federal lands and estimates made from industry respondents, approximately 1,855,000

acres were prescribed burned on all large commercial timberland holdings during the 1975 burning season.

Extensive burning also takes place on other than commercial forest land. Martin<sup>4</sup> estimated that 106,110 acres were burned for range improvement and 192,000 acres to improve muskrat trapping in Louisiana alone. Marshland burns were also prescribed in the Everglades National Park, and in other places unknown to the authors. Total forest and other wild-land burning therefore exceeded the 2.15 million acres reported here for 1975.

#### EXTENT OF SITE PREPARATION BURNING

Of the various types of burns that can be prescribed on forest areas, site preparation burning is usually the most severe, because fuel loadings are usually heavy and burning is done when the fire will be sufficiently intense to maximize fuel consumption.

In Tennessee, Texas, and Virginia almost all of the burning was for site preparation (table 4), and this type of burning accounted for a sizable proportion of the total in most of the other States. Over 40 percent of prescription burning reported by private industry was for site preparation.

Of particular interest is the fraction of site preparation burns in which logging debris has been piled before burning. When debris is properly piled and burned, much of the large material that would remain after a broadcast burn is consumed. However, because more material is consumed, smoke emissions are increased. Smoldering combustion is also increased, and its attendant particulate production is greater than that for flaming combustion.<sup>5</sup> In 1975, nearly one-third of the site preparation burns were conducted with piled debris.

Table 4.--Site preparation and other industry-conducted prescription burning in 11 Southern States during 1975
