1 Key Findings

- The nonpoint source (nps) pollutant of greatest concern to forest management is sediment, which reaches stream channels primarily through erosion. Rainsplash and sheet erosion account for the majority of hillslope erosion.

- Maintaining channel stability and the hydrologic character of the watershed can control stream channel erosion and maintain the sediment/stream energy relationship.

- Silvicultural Best Management Practices (BMPs) are designed to reduce nonpoint source pollution and maintain stream channel integrity so that State water quality standards are met. Where their effectiveness has been evaluated, they have achieved that goal.

- All States have adopted silviculture BMPs and have trained landowners, loggers, and forestry practitioners.

- Twelve of 13 Southern States have measured BMP implementation, but have employed unique approaches to selecting sample sites and conducting on-site evaluations, resulting in different degrees of statistical strength and different expressions of results. Consistency among States is improving.

- While trends in BMP implementation among States cannot be expressed in comparable terms, State reports indicate broad application of BMPs during forestry operations in the South.

- Six of the 13 States have adapted their BMP implementation monitoring program to incorporate procedures contained in the voluntary regional protocol for implementation monitoring endorsed by the Southern Group of State Foresters in 1997. To date, 5 have reported findings based on this approach.

- In general, BMP implementation has been reported to be highest on public land, followed in descending order by forest industry land, corporate nonindustrial land, and private nonindustrial land.

- Professional forestry assistance increases the likelihood that BMPs will be properly implemented.
• Response by State forestry agencies to BMP violations or complaints varies widely. Six follow established, formal interagency agreements that can include referral to enforcement agencies; seven have no formal process for follow-up or referral, but do refer some cases to other agencies. All attempt to work with landowners to correct deficiencies prior to referral to enforcement agencies.

• The Sustainable Forestry Initiative of the American Forest and Paper Association requires that member companies adhere to BMPs on company land. In addition, some forest products companies impose sanctions on timber producers who fail to implement BMPs on noncompany land.

2 Introduction

Best Management Practices (BMPs) are the cornerstone of the forestry community’s approach to protecting water resources during and after forest treatments, commonly referred to as management activities. Design and testing of effective BMPs requires an understanding of basic watershed functions, erosion and sedimentation processes, and interactions between these processes and aquatic resources. Implementation of effective BMPs, once designed, requires continuous education of an ever-changing population of forestry practitioners and landowners. Measuring the success of BMP programs requires regular and credible surveying of BMP implementation. This Chapter addresses each of these topics independently.

3 Methods and Data Sources

Scientific literature provided information on erosion and sedimentation processes, BMP effectiveness, and other BMP benefits. The 13 Southern State forestry agencies provided descriptions and results of BMP implementation monitoring in their States as well as information on formal agreements between State agencies for handling suspected incidents of water pollution from forestry operations.

4 Results

Information on erosion and sedimentation processes and control, BMP effectiveness, and overall benefits of BMPs is presented in narrative form. BMP implementation monitoring information is reported for each State in narrative form and in Table 1. Due to differences in methods for measuring BMP implementation, comparisons of rates among States are not made. For similar reasons the degrees of implementation achieved by regulatory versus nonregulatory programs are not compared.

5 Discussion and Conclusions

5.1 Erosion and Sedimentation Processes

Sedimentation of surface water is the most common nonpoint source pollution concern related
to forest management activities. Sedimentation is the end result of several processes, including erosion; sediment production, transport and deposition; and in-stream morphological processes. In-depth discussion of these processes can be found in Dunne and Leopold (1978); Leopold, Wolman and Miller (1992); Knighton (1993); or Rosgen (1996). This Chapter summarizes portions of those authors’ work to provide background and context for the origin, purpose, and design of BMPs.

5.1.1 Hillslope Erosion

Erosion is the wearing away of the earth’s surface by wind, water, ice, or gravity. For purposes of this Chapter, sediment is the mineral or organic material that is displaced by these forces and delivered to water bodies. Sedimentation is the settlement or deposition of sediment out of the water column.

Erosion and sedimentation are natural processes critical to developing and maintaining stream channel form and function. However, sedimentation at above geologic rates, especially fine inorganic sediment particles, can be of concern (Waters 1995).

Rainsplash, sheetwash, rills, and gullies associated with overland runoff account for most hillslope erosion. Other sources include mass wasting and soil creep (Dunne and Leopold 1978). Mass wasting usually occurs on steep slopes that slide, or slump, when saturated soils weaken to the point of failing to hold in place against gravity. Soil creep occurs on more gentle slopes where soil particles move downslope very slowly. While these are naturally occurring processes, human activities can cause or accelerate them.

Rainsplash erosion occurs when raindrops impact and displace exposed soil. Vegetation and litter cover on the ground absorb virtually all the kinetic energy of rainfall and prevent most rainsplash erosion. Thus, protection of soil cover is an important strategy for minimizing this type of erosion.

Sheet erosion occurs when overland flow travels downslope in an irregular, sheet-like fashion. This type of erosion actually occurs as tiny streams of water moving back and forth across the slope. It can transport already-detached sediment as well as dislodge soil particles. Several site characteristics including soil particle size and pore space, bulk density, and organic matter content affect sheet erosion processes by influencing soil infiltration capacity. The latter three can be directly affected by management activities.

Rill erosion occurs when sheetflow cuts small, separate channels as it moves downslope. Gullies are rills greater than 1 foot wide and 1 foot deep. Exposed soil in rills and gullies is especially vulnerable to rainsplash erosion, so rills and gullies can grow rapidly. Gully erosion can be dramatic, contributing large sediment loads to streams. Nevertheless, rainsplash and sheet erosion generally account for over 70 percent of total hillslope erosion (Leopold, Wolman, and Miller 1995).
5.1.2 Stream Channel Erosion Processes

Channel erosion can be caused by a variety of factors. Most stream channel erosion is caused by the action of in-stream water (Leopold, Wolman and Miller 1995). Water in motion exerts fluid stress, or applied stress, on the streambed and varies with velocity. When applied stress reaches the point that bed particles begin to move, channel erosion results.

The capacity of a stream to carry sediment also increases with stream velocity. At a given flow, velocity varies within channels longitudinally and in cross-section. Thus, channel erosion and sedimentation occur simultaneously. The magnitude of these processes is affected by flow rate; high flows increase channel erosion and low flows increase sedimentation, or deposition.

Rosgen (1996) discusses stream morphology in terms of channel balance, or equilibrium. Sediment size and load vary with stream discharge and stream channel slope, and all exist in a state of dynamic equilibrium. Changes in one variable lead to adjustments by one or more of the others. For example, when sediment delivery to a channel exceeds its transport capacity, sedimentation results. Conversely, reductions in sediment supply below a minimum limit deprive streamflow of sediment and channels can erode.

5.1.3 Hydrologic Responses

Stream equilibrium is also sensitive to hydrologic response of watersheds, especially peak flow. The most important peak flows for channel formation are associated with bankfull events. Bankfull reoccurs about every 1.5 years, on average. During bankfull floods, streambed material is mobile and channels experience change.

Factors affecting peak flow include the area of impervious material, soil infiltration capacity, time of concentration, drainage density, and antecedent soil moisture. Changes in any of these factors can alter peak flows.

5.1.4 Channel Alteration

Channel straightening effectively reduces total channel length over a given elevation change, resulting in increased stream channel slope. Increases in slope frequently increase stream velocity and can cause upstream channel erosion. The effect proceeds upstream until stream slope equilibrium is re-attained.

Constrictions at stream crossings (culverts, bridges) can increase downstream velocity (result in downstream channel scour) and decrease upstream velocity (increase sedimentation above the crossing).

Silviculture BMPs are designed to eliminate or mitigate impacts of management activities on these erosion and sedimentation processes. Natural watershed processes and flow regimes are encouraged and impacts to water quality are minimized by protecting soil cover and soil properties, minimizing channel disturbance, providing adequate road drainage to the forest.
floor, and designing and properly installing stream crossings.

### 5.2 Other Benefits Of BMPs.

The origin of BMPs lies in the Federal Water Pollution Control Act (33 U.S.C. 1251 et seq), commonly referred to as the Clean Water Act (CWA). It directs States to develop programs to control nonpoint-source water pollution and to improve quality of water affected by such pollution. It directs States to identify BMPs and other measures to reduce nonpoint source pollution loadings, and to identify programs for BMP implementation. This law is addressed in more detail in Chapter Aqua-1 and Chapter Socio-3.

Other benefits of BMPs to landowners and the public can be significant. They include improved water quality and aquatic habitat, protected site productivity, and more stable watershed yields. Streamside management zones (SMZs), for example, protect water quality, but also provide habitat for riparian-dependant species, wildlife travel corridors, sources for large woody debris to maintain stream stability and aquatic diversity, and aesthetic benefits. While these benefits exist and can be significant, the exact nature and degree of benefit depend heavily on specific-site conditions and circumstances. These variables make it impractical to explicitly address ancillary BMP benefits in this Chapter, other than to recognize their relevance and need for further study.

BMPs in this Chapter, then, are those designed to protect the chemical, physical, and biological aspects of water quality, and their effectiveness is evaluated in this context.

### 5.3 Effectiveness of BMPs in Protecting Water Quality.

Silvicultural activities include: final timber harvest, intermediate harvests, site preparation, planting, fertilizer application, pest management, road construction and reconstruction, and fire management. Most, but not all, of these activities involve some degree of ground disturbance.

Aquatic conditions most likely to be impacted by forest treatments include water temperature, sediment and nutrient concentrations, stream channel stability, aquatic habitat quality, and toxic contamination. The purpose of silviculture BMPs is to eliminate or mitigate these effects.

Although States report that silviculture is a relatively minor contributor to stream impairment regionally, the pollutant most often associated with silviculture in State Section 305(b) reports is sediment (See Chapter Aqua-1). Forest roads are the greatest source of forestry-related sediment (Waters 1995, Chapter Aqua-3). Thus, BMPs commonly focus on eliminating or mitigating sediment from forest roads.

Some of the relevant research and operational monitoring conducted in the South is reviewed below. Some of the cited studies are highly data-intensive from instrumented watersheds, while others are less data-intensive employing upstream vs downstream observations of specified parameters. Both study types, if carefully designed and implemented, yield valuable information.
from which valid conclusions can be drawn.

5.3.1 Early Research
BMPs are based on either research results, where available, or scientific principles. USDA Forest Service scientists at the Coweeta Hydrologic Research Laboratory conducted much of the research that formed the basis for BMPs in the South. Coweeta was established by the USDA Forest Service in the Appalachian Mountains of southwestern North Carolina to describe and understand the physical and biological processes that influence water as it moves through forested watersheds. Coweeta studies were and are data intensive.

Coweeta scientists conducted one of the earliest evaluations of effects of practicle forest treatments on water quality in 1956 and 1957. A logging operation was conducted in the Stamp Creek drainage of the Tallulah Ranger District on the Chattahoochee National Forest (Black and Clark, undated). Specific operational standards (forerunners of BMPs) were written into the logging contract to test and demonstrate their ability to protect water quality during commercial logging.

Logging practices and road management were designed to control runoff to the adjacent streams. Roads and landings were located away from streams; storm runoff was removed from roads and dispersed onto the forest floor via strategically located broad-based dips; roads were constructed on the contour and limited to less than 10 percent grade; road crossings of streams were minimized and culverts or bridges installed; and road approaches to streams were graveled. Trees were felled downhill and limbed and topped in place; trees were skidded tree-length uphill by cable, butt-end first; skidding was dispersed over the harvest site; and logging slash was left in place except in streams. After the sale, roads and trails were smoothed of ruts and channels, and broad-based dips were restored and maintained to divert road drainage onto the forest floor.

Sediment concentrations in Stamp Creek, monitored throughout the harvest period, averaged 5 parts per million (ppm) as compared to 4 ppm for a nearby control watershed, and 31 ppm for a watershed logged without the applied operational standards. This was one of the first demonstrations that carefully planned and executed commercial logging practices do not degrade water quality. It also demonstrated that water quality can be impacted if protection is not provided.

Other research at Coweeta demonstrated road design considerations that reduce sedimentation from forest roads (Swift 1984). In one study, two sections of an existing logging access road were reconstructed to standards designed at Coweeta. The design called for an outsloped road with no inside ditches, and broad-based dips to divert road drainage. Grades above broad-based dips were kept constant at between 5 percent and 7 percent, outlets from broad-based dips were directed to undisturbed forest floor, outside berms kept road drainage off fill slopes, and brush barriers were constructed at the toes of fill slopes. Several key observations resulted from this study:
• Soil loss from roadbeds was greatest during winter storms and peak logging truck traffic.
• Lower road grades had lower soil losses.
• Cut-slope erosion was reduced if debris was left undisturbed at the toe of the slope during road maintenance.
• Outsloped roads without inside ditches reduced cut-slope erosion on many light-duty roads.
• Shorter fills, greater compaction, and brush barriers at fill-slope toes reduced fill-slope erosion.
• Locating fills away from streams reduced direct sediment input from roads to streams.
• Gravel spread on road beds and grass cover on slopes minimized soil losses.
• Grass cover on cut slopes reduced winter cut-slope erosion.
• Grass cover reduced downslope movement of slumps on moistened fill slopes.
• Gravel cover reduced road-bed rutting and erosion in wet seasons.
• Minimizing road width and curve radius reduced road erosion.

In other research, Swift (1986) tested a number of regionally recommended stream buffer widths and an array of other road BMPs for sediment reduction effectiveness. His findings were:

• Grassed fill slopes reduced sediment travel distance to half of that below “mulched only” and bare slopes.
• Undisturbed forest floor reduced sediment travel distance to half that on a forest floor with litter consumed by prescribed fire.
• Sediment travel distance below forest roads was related to forest floor slope.
• Sediment travel distance from outsloped roads with broad-based dips was not as great as that discharged via culverts.
• Grassed fill slopes and forest floor roughness reduced sediment travel distance by more than 20 feet below forest roads, and brush barriers reduced it more.
• The presence of brush barriers essentially removed the percent slope relationship for sediment travel distance from grassed and ungrassed roadways.
• Ninety-four percent of the soil deposition distances were less than stream buffer widths
recommended by the USDA Forest Service Appalachian Guide standards of 1973 for “slight erosion hazard” soils. Thus, the buffer widths were largely adequate.

- A combination of tested practices can be used to reduce the width of required buffer strips for control of sediment from roads.

Swift recommended that filter strip widths between roads and streams in the Appalachians be based on site conditions and construction and stabilization factors such as grassing slopes, outspooling roads, broad-based dips, cross drains, brush barriers, and forest floor cover.

Examination of State BMPs reveals strong similarities to the above practices that were tested at Coweeta. Indeed, this research has been widely used as the scientific basis for BMPs in Southern States. It also demonstrates that BMPs complement one another when employed as a system of practices.

5.3.2 Operational Effectiveness Monitoring

Several studies have been conducted in the South to test the effectiveness of State BMPs or national forest water quality standards and guidelines. A variety of water quality parameters have been evaluated in a variety of locations, testing the effectiveness of differing practices. All provide valuable insight into the topic and several are summarized below.

Clinginpeel (1989) and Neihardt (1992) measured the effectiveness of BMPs on the Ouachita National Forest in Arkansas and Oklahoma. Clinginpeel focused on BMPs for streamside management areas (SMAs) and for road crossings at streams; Neihardt evaluated BMPs for temporary road crossings of intermittent and ephemeral streams. The measured parameters in both studies were sediment, turbidity in Jackson turbidity units (JTUs), conductivity, alkalinity, pH, nitrites, nitrates, sulfates, and chlorides. Additional parameters in Neihardt’s study were total dissolved solids, hardness, turbidity in Nephelometric Turbidity Units (NTUs), acid, and several metals.

Clinginpeel found that sulfates differed significantly above and below stream crossings, but actual differences were small (1.84 mg/l and 1.94 mg/l, respectively). Above and below measurements at SMAs were statistically different for turbidity (16.1 JTUs and 19.5 JTUs, respectively) and pH (6.13 pH and 6.32 pH, respectively), but remained within State standards. All the other parameters were unchanged. Neihardt found that turbidity measured in JTUs was statistically different, but turbidity measured in NTUs was not.

Both investigators concluded that forestry BMPs, as implemented on the Ouachita National Forest, effectively maintained water quality within State standards.

In a separate monitoring effort, Clinginpeel (1993) evaluated the effectiveness of BMPs for silvicultural herbicide application on the Ouachita National Forest from Fiscal Years 1989 through 1993. Again, stormwater samples were collected above and below treated areas from streams in potentially impacted areas, and analyzed for positive readings of Garlon, Velpar, and
Roundup. In all, 348 water samples were collected from 168 sites. Sixty-nine samples, or 19.8 percent, tested positive for herbicides, but all positive samples were less than one-quarter the EPA limit for the specific herbicide and the toxic limit for fish. He concluded that the BMPs tested effectively protected water quality and fisheries.

In the early 1990s the North Carolina Division of Water Quality and the USDA Forest Service examined the effectiveness of BMPs on a forest road in the Appalachians (North Carolina Division of Water Quality 1994). A long-existing road, which closely paralleled Timbered Branch and its tributaries for about 2 miles and had been a chronic source of road sediments to the stream, was retrofitted with a number of measures designed to reduce sediment loading. They included ditch outlets, sediment traps, berms, weeps, outslopes, humps, and relief culverts. Sediment reduction was assessed qualitatively, and biological monitoring was conducted on the affected streams to determine effects on aquatic species. Improvements in taxa richness and diversity in the aquatic community were attributed to the sediment reduction practices.

The Georgia Forestry Commission, under a CWA Section 319 grant and with quality assurance and quality control provided by the Georgia Environmental Protection Division, monitored 1-year-old harvested sites in all physiographic regions of that State and tested for State turbidity standard violations (Green 1995). Selected sites were 90 percent to 100 percent compliant with forestry BMPs and all included timber harvests and road construction. Turbidity measurements in NTUs were taken upstream and downstream monthly and immediately after runoff-generating storm events. Neither violations of State turbidity standards nor significant increases in turbidity were found.

The Florida Division of Forestry and the Florida Department of Environmental Protection conducted a biological assessment of four commercially harvested sites before and after harvest (Vowell 2001). Sites selected were on forest industry land and were scheduled for harvest as part of normal on-going company operations. Management activities at all sites involved clearcut timber harvest, intensive mechanical site preparation, herbicide and fertilizer application, and replanting. Florida’s silviculture BMPs were strictly adhered to during all operations. Upstream and downstream habitat and biological assessments were conducted before and immediately after activities were performed, and were continued for 2 years. Investigators found no statistically significant differences in parameters measured, between the reference and treated sites. Hence, the authors concluded that Florida’s silviculture BMPs were effective in protecting water quality, aquatic habitat, and overall stream ecosystem health.

The South Carolina Forestry Commission, in cooperation with Clemson University and the South Carolina Department of Health and Environmental Control, evaluated the effectiveness of silviculture BMPs in protecting water quality in all physiographic regions in South Carolina (Adams, Hook, and Floyd 1995). Twenty-seven harvested sites from the Coastal Plain to the Mountains were selected. BMP compliance on the sites ranged from inadequate to excellent, thus bracketing the full range of potential effects. BMP effectiveness was determined by Stream Habitat Assessment (SHA) and benthic macroinvertebrate biomonitoring. Upstream reference sites were used for comparison. Ten sites that rated inadequate for BMP compliance
experienced negative SHA impacts, but only one site experienced moderate macroinvertebrate impairment. On sites where BMP compliance was rated as adequate or excellent, SHA indicated that streams were not impacted. The study did not look at an incremental comparison in SHA or bioassessment with incremental BMP compliance. Sites either passed or failed BMP inspection. Sites that passed BMP compliance inspection scored well on the bioassessment. The authors concluded that BMP compliance inspections appeared to be a reliable and economical surrogate for monitoring BMP effectiveness in South Carolina.

Williams and others (1999) evaluated BMP effectiveness in the South Carolina Piedmont, which they considered the most sensitive physiographic province in the State. The authors studied three harvest, site preparation and regeneration alternatives (with BMPs) for changes in flow, sediment, and nutrients, and compared results to a control watershed. They observed statistically significant increases in observed parameters in all alternatives, but all waters met State water-quality standards. Further, they demonstrated that forestry BMPs reduced sediment yield to one-tenth of that occurring without BMPs.

A report published by the National Council of the Paper Industry for Air and Stream Improvement, Inc. (NCASI 1992) presented numerous documented studies of buffer-strip effectiveness in protecting water quality from silvicultural impacts. It concluded that buffers are effective in reducing transported sediment and pesticides, generally effective in reducing soluble nitrogen and, to a lesser extent, phosphorus delivery to streams.

The above body of scientific literature and monitoring results consistently demonstrates that forest management practices are capable of impacting surface water quality. However, it also demonstrates that appropriate BMPs fully implemented as designed and adapted to the site effectively protect water chemistry, aquatic habitat, and aquatic biota.

5.4 BMP Implementation in Southern States

Pursuant to the Clean Water Act, each State has developed a State Water Quality Management Plan. These plans include BMPs to reduce nonpoint-source water pollution from various sources, including silviculture. State forestry agencies are typically designated by governors as the lead agency for silviculture BMP program management. Consequently, beginning in 1978, each Southern State forestry agency, working in cooperation with other forestry experts and their State’s water quality agency, has adopted BMPs. Most have revised their BMPs since 1990.

BMP implementation is largely voluntary in Southern States, but three (FL, NC, and VA) have linked BMP implementation to other State regulatory programs, making them quasi-regulatory in some circumstances, and BMP implementation became mandatory in Kentucky in July 2000. There are also 15 mandatory Federal BMPs, or conditions, required in all states for exemption of certain silvicultural activities conducted in waters of the United States. See Chapter Socio-3 for a more thorough discussion of Section 404(f), of the CWA. Compliance with these Federal conditions has not been systematically monitored by any agency.
The voluntary nature of State BMP programs precludes establishing permit conditions. Lacking this mechanism, States have employed logger, forester, forest practice purveyor, and landowner education as the primary tool to achieve BMP implementation. Training has traditionally been conducted in cooperation with forest industries, forestry associations and State agencies. Member companies of the American Forest and Paper Association are required by the Sustainable Forestry Initiative Guidelines to meet or exceed State BMPs on company-owned forest land.

To gauge the effectiveness of their educational efforts and to target needed adjustments, State forestry agencies have sponsored or conducted surveys to measure the degree to which BMPs are being implemented. Twelve of 13 States have completed at least one survey. Findings are typically published in formal reports and are available from the respective State forestry agencies. Section 319 (Clean Water Act) funding has supported these efforts.

To correctly interpret monitoring results reported by State, it is essential to understand the history of implementation monitoring and how it has evolved. Implementation (compliance) monitoring of nonregulatory BMPs is unique to the forestry community. While other nonpoint-source sectors such as agriculture, are generally unregulated in the South, the degree of compliance with BMPs for agricultural activities has not been systematically measured or reported. Therefore, survey design standards and monitoring protocols have had to evolve over the 20 years of nonpoint-source program existence. During that time, State forestry agencies have approached implementation monitoring in different ways, degrees of detail, precision, and statistical strength.

Past differences in survey design and statistical strength, and metrics chosen for evaluation within and among States preclude precise reporting of State or regional progress over time. Results range from statistically valid to informative but of unknown statistical strength. Statistical approaches are noted in the individual State summaries below.

It is important to note that, as with sampling approaches, on-site evaluation of BMP implementation and reporting varies among States. Some provide largely qualitative judgments of overall effort; others calculate and summarize compliance with specific BMPs. These are noted in the State summaries.

States have differed in their aggressiveness toward monitoring BMP implementation, a direct reflection of State priorities and available resources. Seven States have completed more than one comprehensive statewide survey (Florida - 10; Texas – 4; Louisiana – 4; Georgia – 3; Arkansas – 2; North Carolina - 2; Tennessee – 2. Louisiana is in the process of data analysis and report preparation of its fourth survey. South Carolina has completed four harvesting and BMP surveys and two site-preparation BMP surveys. Alabama has surveyed compliance in differing manners since 1994, but has produced no formal survey report to date. Mississippi and Kentucky have completed 1 statewide survey, but neither have published a formal report to date. Pursuant to State law, Virginia monitors a percentage of the activities it is notified about. Oklahoma is planning but has not yet surveyed BMP implementation. Louisiana and Kentucky
have been surveyed by university forestry specialists, and the other 10 surveys have been
carried out by the State Divisions of Forestry.

Through the 1990s, CWA Section 319 funds became readily available to State forestry agencies
for BMP program management, and the aggressiveness of implementation monitoring
increased. In order to improve regional similarity in survey design and on-site evaluations, the
Southern Group of State Foresters (SGSF) recommended in 1997 general forestry BMP
implementation monitoring procedures for voluntary use by States (Mimeo from SGSF). To
date, six States (Arkansas, Florida, Georgia, North Carolina, Tennessee, and Texas) have
redesigned their programs to incorporate these recommendations. Others have chosen to
continue their programs as previously structured.

The SGSF monitoring protocol recommends evaluation of specific BMPs in a manner that
requires the evaluator to judge whether each applicable practice was implemented properly and
completely and whether a risk to water-quality exists as a result of noncompliance. Rates are
determined by calculating the percent of applicable BMPs fully implemented and are reported by
BMP category, such as SMZs, and for the entire operation. The protocol also calls for sampling
treated sites in a systematic and predetermined manner to ensure statistical validity.

5.4.1 State Implementation Monitoring Summaries

To compile information contained in the State summaries, written requests were made to each
State forestry agency director in March, 2000, for BMP implementation monitoring data.
Specific information requested included: monitoring design, BMP categories measured,
implementation rates statewide and by physiographic province and ownership category if
available. Responses were received from all States. As noted earlier, all but one (Oklahoma)
reported that they had completed at least one monitoring survey. Following is a brief synopsis of
the information received.

ALABAMA: The Alabama Forestry Commission began conducting annual BMP
implementation surveys in 1994 (Boyce 2000, personal communication), and monitoring is
accomplished by aerial reconnaissance only. BMP survey information is available, although
there is no published survey report as such. Until recently the survey was conducted statewide,
but currently the survey covers half the State each year, alternating between the north and south.
The Commission records all forestry sites via aerial survey, and one site from each county is
randomly selected for BMP implementation monitoring every 2 months. Selected sites must be
well defined as forestry practices, be 1 year old or less, in any stage of completion (on-going,
stopped, or completed), and free from sampling bias (neither size, ownership, or access are
considered). BMP categories are streamside management zones (SMZs), stream crossings,
forest roads, timber harvesting, reforestation/stand management (includes pesticides and fire
breaks), and forested wetland management. The survey evaluation form includes yes or no
questions under each BMP category, and at the end of the evaluation, the site is rated yes or no
as to whether BMPs were adequately implemented overall. The most recent information is for
the survey completed in northern Alabama in fiscal year 1998/1999. The survey rated BMP
implementation as adequate on 93 percent of sites inspected. Of those with streams present, 80 percent were rated as adequate for SMZs. Alabama does not report by ownership category.

**ARKANSAS:** The Arkansas Forestry Commission has completed two statewide BMP monitoring surveys, the most recent one was for the survey period 1998/1999 (Eagle 1999). Sites were randomly selected and permission for access was obtained. The number of sites verified was based on sample percentage estimates for projected statistical accuracy of plus or minus 5 percent, and was distributed throughout the State on the basis of 1997 timber severance tax records. Sites were harvested from 1 to 24 months before survey, and categories of BMPs were forest road construction and maintenance, harvesting, mechanical site preparation, chemical site preparation, SMZs, and harvest planning. Forest industry provided the Arkansas Forestry Commission with closed-out and site-prepared sites for monitoring. Results are reported statewide and by physiographic region and landowner category.

The overall State BMP implementation rate for the 1998/1999 survey was 80 percent. Implementation was 88 percent for planning, 75 percent for roads, 77 percent for harvesting, 79 percent for mechanical site preparation, 80 percent for chemical site preparation, and 81 percent for SMZs.

In the Delta, about 7 percent of all sites were sampled and the overall compliance rate was 85 percent. About 14 percent of the sites in the Ouachita region were visited; the overall compliance rate was about 77 percent. About 12 percent of the sites were visited in the Ozark region, and overall compliance was about 77 percent. About 67 percent of the sites were visited in the Southwest region; the overall compliance was about 80 percent.

Four landowner categories were recognized in Arkansas. The survey reported 75 percent overall implementation for private nonindustrial landowners, 87 percent for forest industry, 96 percent for national forests, and 82 percent for State land.

**FLORIDA:** The Florida Division of Forestry began biennial silviculture BMP compliance surveys in 1981 (Vowell 2000). The most recent compliance report is for the survey completed in 1999. In all 199 sites were monitored, the number was that estimated to be needed to achieve statistical significance at the 95 percent confidence level. Candidate sites must have had silvicultural treatment within the past 2 years and had some part of the site within 300 feet of a stream, lake ≥ 2 acres, sinkhole, or wetland identified in the BMP manual. Sites for the survey were distributed across the State based on the level of timber harvest by county, with at least 1 site for each county that had any harvest activity. Most sites were selected by aerial reconnaissance from aircraft flying over randomly selected township and range lines at an altitude of 800 to 1,200 feet until the target number sites for each county was reached. If flights were not available for any county, sites were selected from the ground, assigned a number, and then drawn by lot.

Florida has 14 BMP categories: SMZs, wetlands, public lands, canals, sinkholes, forest roads, stream crossings, timber harvesting, site preparation, fireline construction, pesticide/fertilizer, waste disposal, wet-weather operations, and emergency conditions. Multiple questions
answerable by yes, no, or not applicable (N/A) were evaluated under each category in the survey form, so the total number of actual silviculture practices evaluated on the 199 sites was 4,997. The yes and no answers were tallied and the percent compliance, exclusive of the n/a answers, was calculated for each site. The survey determined that BMP compliance ranged by category from 91 percent to 100 percent. The statewide compliance rate was 96 percent in all BMP categories. Of the survey sites, 8 percent were on public land, 37 percent were on industry land, and 55 percent were on private nonindustrial land. Statewide compliance rates for the ownership categories were 99 percent, 97 percent, and 96 percent, respectively.

Included in Florida’s BMP survey is opportunity to note whether significant risk to water quality exists on the evaluated site. The 1997 survey found 0.16 percent of the evaluated practices on all sites monitored posed significant risk to water quality. All of the conditions leading to a significant risk were corrected per the Division of Forestry recommendations.

**GEORGIA:** The Georgia Forestry Commission has completed its third BMP implementation survey (Green 2001). The latest survey is the first that conforms to the BMP monitoring protocol endorsed by the Southern Group of State Foresters in 1997. The survey was conducted from fall 1997 through summer 1998 on 386 sites selected from across the State in a stratified random sample. All sites experienced some kind of silvicultural treatment in the preceding 2 years, and represented all land ownership categories in all geographic and physiographic provinces. By ownership, 72 percent of the sites were nonindustrial private, 26 percent were forest industry, and 2 percent were public. By physiographic province about, 6.5 percent were in the Mountains, 34.5 percent were in the Piedmont, 19 percent were in the Upper Coastal Plain, and 40 percent were in the Lower Coastal Plain. BMPs were judged as in compliance (yes), not in compliance (no), or not applicable (n/a) under several BMP categories, and a percent compliance was calculated for each category, for the site as a whole, and for the State. A judgment was made for each BMP not properly implemented, or that was found to have failed, as to whether a significant risk to water quality resulted. Results were also expressed in acres, miles of road and streams, number of stream crossings in full compliance for each BMP category, for the site as a whole, and for the State overall. A total of 6,690 individual BMPs were evaluated over about 43,118 acres.

Percent implementation was calculated in two ways. The number of acres on which BMPs were properly implemented was calculated for each BMP category, and the number of applicable BMPs properly implemented was calculated. Therefore, BMP implementation was reported as a percentage by acres and a percentage by BMP. Categories for BMPs and respective compliance ratings were SMZs (80.9 percent), stream crossings (58.8 percent), main haul roads (76.6 percent), timber harvesting (87.3 percent), mechanical site preparation (96. percent), chemical applications (99.3 percent), control burning (61.5 percent), and artificial regeneration (93.4 percent). Statewide BMP implementation compliance was estimated at 78.7 percent for all BMP categories in all land ownerships and all physiographic regions. Statewide compliance on the number of acres assessed was 98.2 percent. By landownership, BMP compliance by acres assessed and BMPs implemented, respectively, was 97.4 percent and 75.4 percent on private nonindustrial, 99.1 percent and 86.3 percent on forest industry land, and 99.4 percent and 84
percent on all public land.

Of particular concern to the Georgia Forestry Commission were stream crossings. However, the Commission noted that many of the out-of-compliance stream crossings existed before silvicultural treatments were conducted and were not specifically related to forestry operations. Future surveys will include only treatments specifically related to the forestry activities.

**KENTUCKY:** The Kentucky Division of Forestry BMP monitoring program estimates BMP effectiveness at mitigating nonpoint-source runoff (Stringer 1997a). The University of Kentucky conducted a BMP survey from September 1995 to April 1997 (Stringer 1997b). The BMP categories monitored included SMZs, roads, trails, landings, and stream crossings.

A total of 100 timber harvest sites were located for systematic sampling from the three physiographic regions of the State. The three regions are Area 1 (Jackson Purchase/Western Coal Field/Pennroyal), Area 2 (Inner and Outer Bluegrass and the Knobs), and Area 3 (Appalachian Plateau and Cumberland Mountains).

Of the 100 sites monitored, evaluators determined that only 80 needed “active BMPs”. Those 80 were evaluated for BMP implementation.

Monitoring indicated that, of those 80 monitored sites, 35 percent had BMPs that were effective, 12.5 percent had BMPs that were partially effective, 10 percent had BMPs that were not effective, and 42.5 percent had no BMPs. In other words, more than half (52.5 percent) of the 80 sites either had no BMPs or the BMPs were ineffective, and less than half (47.5 percent) had BMPs that were effective or partially effective.

Area 2 had the highest incidence of “BMPs Not Used or Not Effective” (59 percent), and Area 3 was evenly split 43.2 percent between “BMPs Not Used or Not Effective” and “BMPs Effective or Active BMP Use Not Needed”.

Nonindustrial private land had slightly less implementation and effectiveness of BMPs than the other landowner categories. On a scale of 1 – 5 (1 is worst and 5 is best), public ownerships rated about 4.5 for BMP use and effectiveness, forest industry rated about 3.75 to 4, and nonindustrial private land ownership rated about 3.

**LOUISIANA:** The Louisiana Department of Agriculture and Forestry has conducted four BMP implementation surveys (1991,1994,1997,and 2000). The most recent published report was for the 1997 survey (Hughes and Feduccia 1999), and the 2000 survey was not published in time for inclusion in this SFRA study. The number of survey sites necessary to determine with 95 percent confidence if forestry BMP implementation in Louisiana was at least 80 percent in 1997 was estimated at 256; 266 individual sites were actually surveyed. Sample sites were randomly selected by aerial observation, regardless of ownership, and the number of sites in each parish was based on 1996 timber harvest volume. Land ownership categories were forest industry, corporate non-forest industry, nonindustrial private, and public (Federal, State and local governments). The geographic regions were Delta, Northwest, Southeast, and Southwest.
Categories for BMPs were SMZs, road construction, timber harvest, site preparation and reforestation, and fireline construction. The survey form showed the number of specific BMPs in each category that were assessed. Implementation of BMPs was noted as: exceeds; full implementation; minor departure; needed but not applied; and no action required. Exceeds, full implementation, and minor departure were categorized as implemented; needed but not applied was considered not implemented.

Each survey site was given both an overall qualitative and quantitative implementation rating. The qualitative rating was in answer to the yes or no question, “Do you feel there was adequate BMP implementation on this site?” The quantitative rating was calculated as the percentage of implemented BMP guidelines on the site.

The overall statewide qualitative implementation rate was 83 percent, and the statewide quantitative implementation rate was 93 percent. Quantitative geographic implementation rates were 93 percent in the Delta, 94 percent in the Northwest, 92 percent in the Southeast, and 96 percent in the Southwest. Quantitative implementation rates by ownership category were 97 percent for forest industry, 95 percent for corporate non-forest-industry, 91 percent for nonindustrial forest, and 93 percent for public. Qualitative rates were not reported for geographic or landowner category.

**MISSISSIPPI:** The Mississippi Forestry Commission conducted a forestry BMP implementation survey in 1994, although there is no published implementation monitoring report (Sampson 2000, personal communication). Fifteen tracts harvested during 1993 were randomly selected from among all landowner categories from each of Mississippi’s 82 counties, for a total of 1,230 tracts sampled. The survey estimated Statewide BMP implementation at 87 percent. The Commission recommended corrective measures on the surveyed sites needing BMPs. A new BMP monitoring strategy is being developed.

**NORTH CAROLINA:** The North Carolina Division of Forest Resources has instituted voluntary BMPs to ensure that the nine mandatory Forest Practice Guidelines (FPGs) related to water quality are met by forest management operations in the State (White 1992). Mandatory FPGs are required for exemption of forestry operations from the Sediment Pollution Control Act passed in the early 70s. The FPGs are performance standards that must be complied with, while BMPs are the more specific on-the-ground activities that, when applied, should result in maintaining compliance with the FPGs.

The Division conducted forestry BMP surveys in 1995 and 1996 (Hensen 1996) and is in the process of completing a 2000 survey. Two hundred timber harvest and 23 site-preparation sites, most of which were harvested between spring 1995 and spring 1996, were selected for the 1996 survey. Tracts had to have potential for affecting some water body, and were randomly selected and distributed throughout the State based on each county’s timber production. BMP categories were permanent roads, skid trails and temporary roads, SMZs, landings, and site preparation. Each category had a number of questions to be answered as yes, no, or not applicable (N/A), and each site received an overall rating of no effort, poor, fair, good, or
excellent. Landowner categories were public, industrial, and nonindustrial private. There was no physiographic or geographic stratification in the survey, but there was a slope category broken into three slope ranges: flat (0-5 percent), hilly (6-25 percent), and steep (>25 percent).

Overall statewide BMP implementation was rated at 95 percent as either good or excellent. Public land was rated at 100 percent, industry land at 90 percent, and nonindustrial land at 76 percent. There was no discernable BMP implementation pattern based on slope.

**OKLAHOMA:** Oklahoma is in the process of conducting its first forestry BMP implementation survey at the time of this Assessment (Atkinson 2000, personal communication).

In 1997, 200 recently harvested sites were located through aerial survey across South Carolina for BMP compliance evaluation. Sites were distributed in proportion to timber harvests in each county relative to the whole State. Three visits were made to each site: one after harvest for compliance with harvest BMPs, one after site preparation for compliance with site preparation BMPs, and a third visit 2 years after harvest. The final visit examined site stabilization, BMP effectiveness, species and regeneration method used, and any ongoing erosion from silvicultural activities.

Harvesting BMP ratings were 98.6 percent acceptable for road systems, 86.7 percent acceptable for road stream crossings, 83.7 percent acceptable for SMZs, and 89.0 percent acceptable for logging systems. Statewide and overall, 91.5 percent of harvesting BMP categories were rated as acceptable.

Site preparation category ratings were 95.9 percent acceptable for mechanical treatments, 100 percent acceptable for herbicide applications, and 100 percent acceptable for prescribed burning. No sites had minor drainage activities to be evaluated in this survey. Statewide and overall, 98.0 percent of site preparation BMPs were rated acceptable. Visual observations of groundcover during the second and third visits indicated that naturally occurring vegetation generally stabilized harvested areas after one growing season, even in high-traffic areas and where mechanical site preparation occurred.

Findings by landowner categories were: nonindustrial private with under 1,000 acres, 87 percent acceptable BMPs; nonindustrial private with over 1,000 acres, 94 percent; forest industry, 98 percent; and public, 100 percent.

There was no physiographic reporting in the 1997 survey, but 11 sites with inadequate harvest system BMPs were noted in the Piedmont and 6 in the Coastal Plain.

**TENNESSEE:** The Tennessee Forestry Division reported two forestry BMP surveys -- one
conducted in 1993 and one in 1996 (Tennessee Department of Agriculture, Forestry Division 1996). The survey form and protocol were modified in 1995, so results of the two surveys are not entirely comparable. In the second survey, 200 timber harvest and associated road construction sites were evaluated in all physiographic regions. One hundred seventy-nine sites were randomly selected, and 21 sites were investigated in response to water-quality complaints. Monitoring was conducted within 6 months after all activities were completed. Sites selected randomly were not reported separately from those visited due to complaints, so the overall results are not completely unbiased. During the survey, investigators noted instances where water pollution occurred or was likely to occur due to lack of BMPs or improper use of BMPs. In such instances, the operator or landowner was contacted and advised of necessary corrective action.

Examiners noted whether guidelines under each BMP category were implemented or whether the BMP was not applicable to that site. Responses were summed to determine the BMP implementation rates for the forestry practices and the operation as a whole. From the 200 sites evaluated there was a total of 1,787 individual BMP observations. Ratings for BMP categories were: roads, 59.5 percent compliance; SMZs, 70.5 percent compliance; stream crossings, 59.8 percent compliance; timber harvesting, 47.6 percent compliance; and waste disposal, 87.0 percent compliance. Only one site had been mechanically prepared, and all BMPs were implemented on that site. There were no observations in either the tree planting or fireline construction categories.

The overall statewide BMP compliance rate for the 1996 survey was 62.9 percent for all sites visited – the randomly chosen ones and those visited in response to water-quality complaints. Monitoring results were not broken out by landowner group or physiographic province.

The most recent survey was conducted between June 1998 and August 1999. A number of yes, no, or not applicable assessment questions were evaluated under the various BMP categories. An evaluation of “significant risk” was added for each assessment question. The purpose was to assess whether failure to properly implement a specific BMP posed significant risk to water quality. The yes and no answers were summed and an overall site compliance rating was calculated.

One hundred fifty timber harvest sites were randomly selected for investigation by aerial reconnaissance and from knowledge of harvest activities gathered from Texas Forest Service personnel. The sites were distributed among the counties based on estimated annual timber harvest. Sample sites were located without regard to ownership or proximity to water.

Results are reported by BMP category, ownership, and type of operation. BMP categories and overall compliance rates reported were: permanent roads, 94.1 percent; skid trails/temporary roads, 77.5 percent; stream crossings, 66.7 percent; SMZs, 86.0 percent; site preparation, 96.2
percent; landings, 98.8 percent; and wetlands, 86.7 percent. Overall State compliance for all categories was 88.6 percent.

Compliance by ownership category was: Forest Service, 97.9 percent; forest industry, 94.2 percent; and nonindustrial private, 81.2 percent. Compliance by type of operation was: clearcut, 85 percent; partial cut, 93 percent; thinning, 92 percent; and site preparation only, 93 percent.

In general, as terrain steepness increased, compliance decreased. Also, the Texas Forest Service reported for the first time a statistically significant increase in BMP compliance when:

- a forester was involved in the timber sale,
- the logging contractor attended the BMP training workshop,
- the landowner was familiar with BMPs, and
- there were BMPs in the timber-sale or site-preparation contract.

**VIRGINIA:** Virginia State law requires notification of Virginia Department of Forestry within 3 days of initiating timber harvest (Austin 2000). Semi-annually, the Department randomly selects 30 timber harvests from this database for BMP audits. Monitoring categories are stream crossings, water control structures, seeded areas, SMZs, trail/road grade, rutting, gravel/mats, oil spill/trash, and other. To be in full compliance, 100 percent of applicable BMPs at the audit site have to be 100 percent implemented and meet 100 percent of the technical specifications of the BMP manual. Measured in this way, compliance has ranged from 16 percent in 1991, to 7 percent in June 1999. Effort to implement BMPs was noted on 90 percent of the sites visited. The field evaluator indicated that 90 percent of the sites were experiencing no related water quality impacts, but 38 percent exhibited potential for impact.

The above summary of State reports illustrates the variety of BMP monitoring approaches and levels of monitoring effort employed by Southern State forestry agencies over the past 20 years. This reflects the priority placed on BMP implementation monitoring by States, as well as human and financial resource constraints.

The summary also demonstrates the difficulty of discerning actual rates of compliance with specific BMPs. Many on-the-ground determinations of BMP implementation are qualitative by design, adding to the difficulty of comparing or reproducing results.

It is noteworthy that most State surveys are conducted after on-the-ground activities have ceased. Thus, it is possible that water quality impacts could occur but stabilize prior to the site being evaluated.

Given the nature and limitations of the reported data, three important and consistent patterns emerge. First, BMPs are being implemented broadly across the South, and the rates of
implementation, while subject to interpretation, appear to be generally high. Second, implementation of BMPs tends to be highest on public land, followed in descending order by forest industry, corporate nonindustrial, and private nonindustrial forest land. Third, forest management operations that involve advice and oversight by forestry professionals exhibit higher BMP implementation rates than operations not having that involvement.

On the whole, the State forestry agencies report increasing BMP implementation over time. They credit this improvement to the on-going efforts to educate those involved in forestry about BMPs and the benefits of BMPs, technical assistance, changing legislation in some of the States, increasing partnerships with forest industry, and increasing efforts of forest industry (including industry imposed penalties on noncomplying timber producers and forestry professionals) to get BMPs implemented.

These findings indicate that the current approach to achieving BMP implementation is having positive results, particularly on large ownerships. The challenge remains large and persistent, however, to achieve equal success on nonindustrial private tracts, given that they are owned by almost 5 million individuals (Health 1, Timber 2), and a relatively small percentage of such individuals who typically receive professional forestry assistance prior to treating their land (Chapter Socio-5).

5.5 Regulatory Versus Nonregulatory Approaches

Various means are available for comparing regulatory and nonregulatory water quality management approaches. Advantages and disadvantages could be listed and discussed for such factors as cost, operational flexibility, and overall program effectiveness. Such a discussion, while perhaps interesting, would be necessarily complex and tedious and not likely to result in definitive conclusions. Another approach is to discuss means (including enforcement actions) that are employed within States to ensure BMP implementation, when noncompliance is either discovered during monitoring or brought to a State’s attention via citizen complaint.

Traditionally, water-quality management agencies have depended on regulatory approaches (permits and permit conditions) to control discharges into State waters. Compliance has been monitored in different ways, ranging from regular site inspections to self-monitoring and reporting. These approaches were developed for and have long been employed to control point-source discharges.

Silviculture is a nonpoint source of pollution. The CWA stipulated that nonpoint-source pollution control is to be accomplished through BMPs identified by each State, but BMP implementation is not mandatory under the CWA. Best Management Practices are administered by State forestry agencies, whose regulatory authorities are generally limited to fire control. This combination of factors explains why a nonregulatory approach to BMP implementation still persistent today in nearly all States.

The common goal of both approaches is the protection of water quality. States utilize preventive
practices and follow-up actions when degradation is noted or complaints are received. While
effectiveness of State regulatory programs is not discussed in this Assessment, formal follow-up
procedures employed by States for forestry BMPs are described here. This description
illuminates potential consequences, or disincentives, of noncompliance.

Following are summaries of current State procedures in place to respond to noncompliance.
They are based on information received from State forestry agencies.

ALABAMA: Alabama has a nonregulatory BMP program (Boyce 2000, personal
communication). Through cooperative agreement, the Alabama Division of Environment refers
suspected water-quality complaints due to forestry to the Forestry Commission. A forester visits
the area to determine if a forestry-related water-quality problem exists, or could develop, due to
lack of or inadequately implemented forestry BMPs. If that situation exists, the responsible
party is contacted and provided recommendations for corrective action. A follow-up visit is
made, and if corrective action is not taken, the problem is referred back to the Division of
Environment for appropriate enforcement. The number of BMP complaints acted on by the
Forestry Commission in 1998, 1999, and 2000 were 17, 17, and 42 respectively.

ARKANSAS: Arkansas has a nonregulatory BMP program (Eagle 2000, personal
communication). The Arkansas Forestry Commission has the lead role for supervising the
silvicultural portion of the nonpoint source water pollution control program. The Arkansas
Division of Environmental Quality (DEQ) has regulatory water pollution control authority in
Arkansas, and a formal memorandum of understanding exists between the Forestry
Commission and DEQ. Complaints or violations of water quality suspected to be due to forestry
are first referred to the Forestry Commission, which works with the landowner and operator to
rectify any identified cause(s) of pollution. If the landowner or operator fails to correct the
cause, the incident is referred back to the Division of Environmental Quality, which has
authority to institute civil action and assess fines of up to $10,000/day. The Forestry
Commission estimates acting on about four such complaints or cases per year from 1998 –
2000.

FLORIDA: Florida has a nonregulatory BMP program, but State permits are required for forest
roads, stream and wetland crossings, ditching and borrow pits (Vowell 2000). As part of its
BMP monitoring program, the Division assesses risk from noncompliance with specific BMPs.
When it is determined that a BMP has not been implemented properly, an assessment of
“significant risk” is made. Significant risk exists when a situation presents imminent and
substantial danger to designated beneficial uses of State waters. In these cases, the Division
recommends corrective measures to be taken by the landowner. Although no formal
memorandum of understanding exists between the Division of Forestry and the Department of
Environmental Protection, if recommended action is not taken, the landowner is referred to the
appropriate regulatory authority. This has occurred an estimated six times from 1998 – 2000.

GEORGIA: Georgia has a nonregulatory forestry BMP program. Incidents of suspected
forestry-related water pollution are first referred to the Georgia Forestry Commission, which
investigates the site (Green 2000, personal communication). If a water-quality problem is attributable to forest practices, corrective measures are recommended to the operator or landowner. If recommendations are implemented and the problem is corrected, no further action is taken. If the recommendations are not taken and the problem persists, incidents are referred to the Georgia Environmental Protection Division for enforcement action. This has occurred five times between 1998 and 2000.

Additionally, the Georgia Forestry Commission submits a regular report of water-quality violators to the forest industry members of the Sustainable Forestry Initiative (SFI), who individually can stop accepting wood from those producers at their mills. The SFI mills that receive wood from producers on that list contact those producers and tell them they are at risk of not having their wood accepted at their gates.

Likewise, the State Board of Registered Foresters in Georgia has adopted a system for imposing sanctions against registered professional foresters for BMP noncompliance (Green 2001). In cases of BMP noncompliance, registered professional foresters may face penalties including consent agreement, fines, license suspension, license probation, and public reprimand.

**KENTUCKY:** Kentucky instituted a new regulatory timber harvesting BMP program on July 15, 2000 (Lowe 2000, personal communication). Loggers are required to use appropriate BMPs, and a Kentucky Master Logger (a logger who has completed the logger-training program of the Kentucky Division of Forestry) must be on site and in charge of any commercial logging operation. The Division visits and inspects logging operations for compliance. Noncompliance results in a written warning to the logger describing what is out of compliance and what needs to be accomplished to bring the operation into compliance. If the written warning fails to bring corrective action, an informal conference is held with the logger. Failing correction, a notice of violation is issued, and, as a last step, a special order is issued. The special order provides for shutting down a portion of the operation until compliance is achieved. Where noncompliance is serious enough to pose a significant threat to water quality, an emergency order can be issued which will shut down the entire operation without going through the first three steps. If these steps for attaining BMP compliance fail, the Division of Forestry can initiate administrative hearings, fines, or court actions. Prior to this program, the Division of Forestry reports that they referred several silviculture-related water-quality cases to the Division of Water, but their exact number and resolution status are unknown.

**LOUISIANA:** Louisiana has a nonregulatory BMP program. Louisiana has no formal process in which suspected forestry-related water-pollution cases are handled separately from any other suspected nonpoint-source pollution problem (Feduccia 2000, personal communication). When the Louisiana Department of Agriculture and Forestry is called out on a site with suspected forestry water-quality violations, it may make suggestions for BMPs that may be missing or inadequate. No formal Departmental process exists for dealing with specific forestry operations suspected of causing water pollution, nor does any formal agreement for addressing such occurrences exist between the Department of Agriculture and Forestry and any other State agency.
MISSISSIPPI: Mississippi has a nonregulatory forestry BMP program (Sampson 2000, personal communication). In cases of BMP noncompliance, the Commission makes recommendations to correct the problems. No formal interagency agreement exists for referrals.

NORTH CAROLINA: North Carolina has a set of mandatory Forest Practice Guidelines (FPGs), which are performance standards specified for various forest management categories, but has voluntary forestry BMPs designed to ensure attainment of the FPGs (White 1992). The North Carolina legislature passed the Sediment Pollution Control Act, which requires a site plan for land-disturbing activities, and is enforceable by the Division of Land Resources. The Act initially exempted forestry, but in 1989 it was amended to exempt forestry only so long as forestry activities are conducted in accordance with FPGs.

In cases of citizen complaints or otherwise-reported incidents of Guideline noncompliance, a Division of Forest Resources representative visits the suspected sites and recommends remedial action with a timetable to the operator. If the responsible operator cannot be found, the recommendation is given to the landowner. If recommendations are not implemented and a water-quality problem(s) continues, the incident is referred to the Department of Land Resources, the Division of Water Quality, or the Division of Forest Resources law enforcement staff for action. Activity can be stopped and a fine of $1,000 levied, a sediment plan required within 30 days of disturbance, specific cleanup measures required, and a $500/day fine levied if cleanup is not accomplished. The site is monitored until cleanup is finished.

Since 1990, over 26,000 Guideline evaluations have been conducted, about 1,900 notices of noncompliance have been issued, and approximately 100 cases referred for enforcement to other State agencies (27 since 1998). Cases resolved without the need for punitive action have not been formally tracked.

OKLAHOMA: Oklahoma has a nonregulatory forestry BMP program (Atkinson 2000, personal communication). Suspected forestry-related water-quality violations are inspected by Forestry Services and any necessary corrective action is recommended. If the operator or landowner does not take the recommended action and a water-quality violation persists, the incident is referred to the Department of Environmental Quality for necessary enforcement action. There is no formal interagency agreement for referrals of this kind. In addition, some major forest industries in Oklahoma accept wood at their gates only from loggers who have completed Master Logger training, which includes a module on forestry BMPs.

SOUTH CAROLINA: South Carolina has a nonregulatory silviculture BMP program with regulatory backup provided by the South Carolina Department of Health and Environmental Control (DHEC). A formal memorandum of understanding between the South Carolina Forestry Commission (SCFC) and DHEC defines the role of each agency in preventing or correcting water quality impacts from forestry operations. The Department of Health and Environmental Control refers all forestry-related water-quality complaints to SCFC for investigation. The Forestry Commission recommends corrective actions to the landowner and forestry operator, where noted problems can be resolved. Sites on which SCFC recommendations are not implemented
within 30 days are referred back to DHEC for enforcement action.

Additionally, SCFC has developed a Courtesy Exam Program, unique in the Southern States, as a proactive means to encourage proper BMP implementation (Jones 2000). In this program, active forestry operations are located through weekly aerial reconnaissance of major drainages, through voluntary prior notification by foresters, loggers or site-preparation contractors, through complaints from the public, through the DHEC, and through other sources. Permission is secured from landowners to visit individual sites, the operators are contacted, and BMP foresters inspect the sites for BMP compliance. Written recommendations based on the site visits and BMP manuals are provided to the landowners and contractors, and the BMP foresters make follow-up visits after project completion to see if BMPs were followed and if related water-quality problems occurred.

Monthly courtesy exam summaries are provided to DHEC and made available to others upon written request. Summaries include a list of operators who failed to implement BMPs and may have created unresolved water-quality problems. Individual forest products companies have used this information to take corrective actions that they deem necessary. Actions have included refusal of wood at the mill, mandatory state monitoring, and additional training requirements (Adams 2001). The courtesy exam program is credited for achieving high rates of BMP implementation in South Carolina. In 1999, for example, BMP compliance was 99 percent on sites that underwent a courtesy exam.

**TENNESSEE:** Tennessee has a nonregulatory BMP program (Arnold 2000, personal communication). In incidents of suspected water pollution due to forestry, investigators from the Department of Agriculture are called in to assess the sites and recommend any necessary corrective measures. If, after reasonable efforts by that Department, an operator or landowner fails to cooperate or comply with recommendations, the Department of Environment and Conservation may take appropriate enforcement action. During 1998-2000, 126 cases were referred by the Division of Forestry.

The Tennessee State Legislature passed House Bill 2846 in 2000, which gives stop-work authority to the Commissioner of Environment and Conservation. When water pollution occurs because an operator fails to use forestry BMPs, the Commissioner, after consultation with the Department of Agriculture, may issue a stop-work order, and shall at the same time notify the landowner that a stop-work order has been issued. The operator must then cease part of or all activities contributing to the pollution. The order will remain in effect until the operator implements the Forestry Division’s recommended BMPs that eliminate and prevent further pollution from forestry activities at that site. Any operator who receives a stop-work order must, for the next 2 years, notify in writing the Commissioner of Agriculture and the Commissioner of Environment and Conservation at least 10 days prior to beginning any silvicultural activity. Information must include the names of the landowner and operator, the location of and acreage of proposed silvicultural activity, and the beginning and expected ending dates of silvicultural activities.
TEXAS: Texas has a nonregulatory BMP program (Carraway 2000, personal communication). There is no formal State interagency agreement by which BMP noncompliance is addressed. However, there is a State Coordinating Committee consisting of all regulatory agencies (Texas Natural Resources Conservation Council, U.S. Fish and Wildlife Service, U.S. Army Corps of Engineers, and U.S. Environmental Protection Agency) and the forestry community (Texas Forest Service, Texas Soil and Water Conservation Board, Texas Forestry Association, Texas Loggers Council, forestry consultants, Texas Parks and Wildlife Department, forest industry, and others). In cases of reported or discovered BMP noncompliance, or nonpoint-source water pollution from forestry operations, the Service provides advice for recommended BMPs and seeks cooperation of the logger and/or landowner. Texas has a “bad actor” provision in its water quality law that allows pursuit of a repeat offender, but it has rarely, if ever, been used with respect to silviculture. The Texas forest industries that subscribe to the Sustainable Forestry Initiative have taken it upon themselves to audit timber producers supplying their mills, and producers found in noncompliance with BMPs are counseled to improve BMP implementation. Those who do not comply with Texas recommended BMPs are not permitted to deliver wood at these mills. This arrangement is believed to be producing an improving trend in BMP implementation in Texas, but there are many small timber industry mills, that do not subscribe to the Sustainable Forestry Initiative.

VIRGINIA: Virginia has a nonregulatory BMP program, but it does have mandatory harvest notification no later than 3 working days after the initiation of harvest operations (Poirot 2000, personal communication). Further, the Silvicultural Water Quality Law, effective 07/01/1993, authorizes the Virginia Department of Forestry to require corrective measures for silvicultural operations causing, or with potential to cause, sedimentation of State waters. In cases where the Department enforces this law, the first step is issuance of a Notice of Required Action, which is an informal description of what needs to be done to correct the problem. If that fails to bring resolution, an informal conference is held with the operator. The next step could be issuance of a Special Order, which details proof of sediment pollution and contains step-by-step prescription of necessary corrective measures with schedule for work. If the operator fails to comply with the Special Order, a formal hearing is held to determine if the Special Order was violated. Finally, civil fines of up to $5,000 per day can be assessed. This authority also includes issuance of stop-work orders. Formal actions taken by the Department of Forestry in 1998, 1999 and 2000 total 199, 272, and 540, respectively. The increase in 2000 is attributed to addition of compliance monitoring staff.

Other forestry-specific State laws include the Chesapeake Bay Preservation Act and local land-use tax rules. These acts and rules exempt forestry from certain requirements, or exempt forest land from certain taxes, provided that BMPs are implemented and verified by the Department of Forests. Monitoring of BMPs for compliance with the Silvicultural Water Quality Law is done coincidentally on about 240 randomly selected tracts per year through quarterly administrative review in the six Department regions, and through the semiannual BMP implementation and effectiveness monitoring survey.

Analysis of this topic leads to several broad observations:
• The nonregulatory approach utilized in Southern States over the past 20 years to protect forest water resources is nontraditional, unique, and still evolving. Its dependence on practitioner education, direct landowner assistance, and systematic monitoring of program effectiveness has gained momentum and widespread acceptance in the forestry community.

• The silviculture BMPs recommended by Southern States are grounded in science or are based on scientific principles. While there are differences among States in specific individual BMPs applied on the ground (SMZ widths for instance), consistency among States is generally strong and continues to increase. Where tested, BMPs have proven effective at maintaining State water quality within applicable standards. Additional scientific validation of BMP design will serve to refine their application to fit site-specific conditions.

• Success of the nonregulatory approach requires continual education efforts targeted at the ever-changing groups and individuals who own and treat the South’s forests.

• Documenting the effectiveness of these approaches and their efficacy in protecting water resources is complex, costly, and still evolving. Southern States vary widely in their methodologies and commitment of resources for BMP monitoring.

6 Needs for Additional Research

• Additional documentation of the scientific basis for BMPs and studies of BMP effectiveness are needed to evaluate them in representative ecological provinces in the South. Key topical areas should include stream crossings, SMZ harvesting options, and overall SMZ management. Chemical, physical and biological water-quality parameters and stream channel stability indices should be documented for different stream types.

• Reasons that landowners comply or do not comply with BMPs are not well understood. Additional information of this kind would be useful for targeting outreach efforts and adjusting state programs.

• Resource benefits provided by BMPs other than water-quality protection should be studied and documented. This information would be useful for encouraging landowner acceptance and could identify needed modifications in BMPs.

• Effects of nontimber uses of forests, such as off-road vehicle use and equestrian crossings, are not well documented, but are potentially significant. Effects of these uses may be similar to those of roads and skid trails (concentrated traffic in small, potentially high impact areas). Science-based BMPs could be tailored for these and other common forest uses.
• Economic costs of BMPs to landowners are not well understood, and should be documented.

7 Acknowledgments

The authors thank Tim Adams, Jeff Vowell, Lloyd Swift, and Margi Swisher Jones who served as the panel of experts in February 2000. They provided invaluable assistance in developing the plan of work and suggested references to address this Assessment question. Crystal Lovett with Environmental Defense provided important input to the panel of experts and also provided suggested references as well.

Thanks are extended to the 13 Southern State forestry agency directors and their staffs for information and willing cooperation. Finally, appreciation is expressed to the anonymous peer reviewers who provided the authors the benefit of their expertise to improve this Chapter.
